## Where do web surveys work?

A meta-analysis of response rate experiments across countries

*Jessica Daikeler\*, Henning Silber\*, Michael Bosnjak\*\**

*\* GESIS, \*\* ZPID*

- Cross-cultural research questions and thus cross-national datasets become increasingly important in globalized world
- Large international surveys do still stick to traditional survey modes, however face-to-face surveys are cost-intensive and inflexible -> increasing number of offline recruited internet panels around the world and international attempts for web-based cross-cultural data collections (e.g., CRONOS Panel, OPPA)
- Major challenges in web-based data collection: Nonresponse bias and coverage
- Nonresponse rate is not equal with nonresponse bias. Nonetheless, those two concepts are strongly related and moderated by survey design features such as the survey population (Groves & Peytcheva 2008)

- Existing meta-analytical research that aimed at explaining web response rates with survey design factors could not explain large parts of response rate heterogeneity (Manfreda et al., 2008; Shih & Fan, 2008; Daikeler et al., 2018)
  - *Found on average 12%-points lower web response rates compared to traditional survey modes*
  - *Significant survey design factors (Daikeler et al., 2018):*
    - *survey prenotifications - are less effective in web modes*
    - *sample recruitment strategy - web surveys work in panels or pre-recruited lists better as for one time recruited subjects*
    - *solicitation mode - web surveys work better with an email solicitation compared to mail or telephone*
    - *target population - web surveys work better for students or members than for business association or the general population*
    - *number of contact attempts - more contact attempts work better in other modes than the web*
- *Explained effect size heterogeneity  $\leq 8\%$*

- Cross-cultural differences affect response behavior (e.g., Johnson et al. 2005; Smith & Fischer, 2008; Stark et al. 2018)

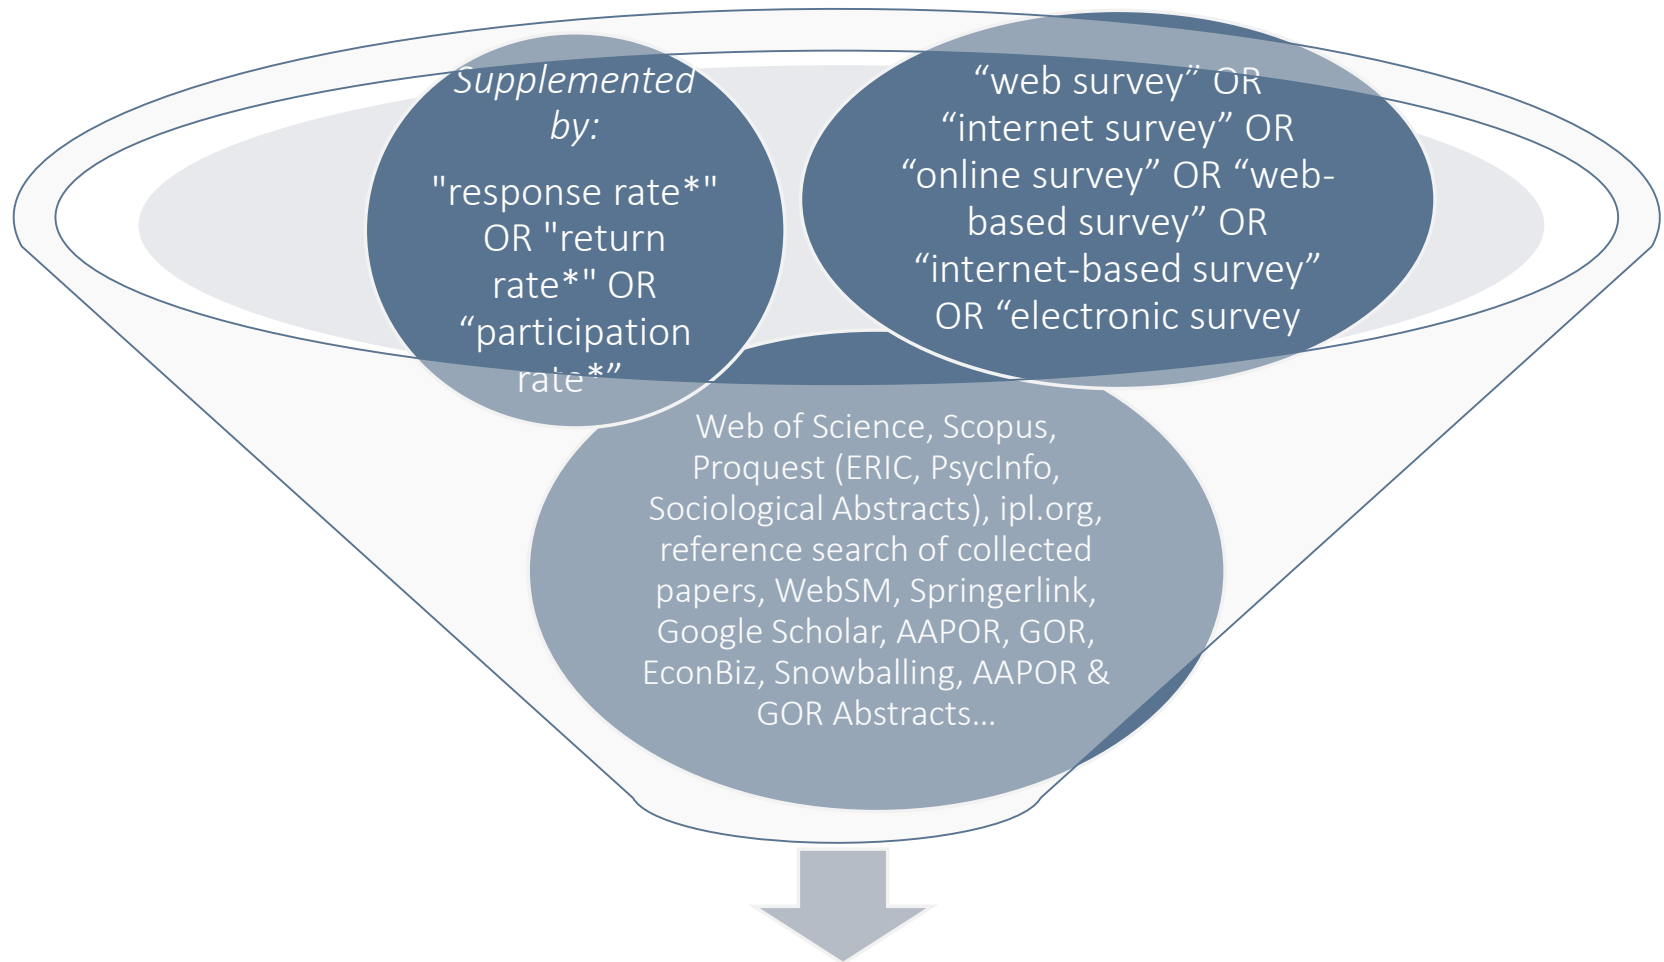

At least three aspects why online survey response rates might differ across countries:

- Social and economic factors (e.g., Rammstedt et al. 2017; Stark et al. 2018)
  - Education
  - GDP
  - Annual population growth
  - Mean population age
- Technological factors (e.g., Mohorko, et al. 2013)
  - Internet Coverage
  - Cellphone Coverage
  - Internet users
- Country-specific survey climate (e.g., Babier et al. 2016; Beullens et al., 2018)
  - Frequency of surveys
  - Country-specific response behavior

To our knowledge no previous study attempted to examine web response and refusal behavior from a cross-cultural perspective

Our research goals are to...

- I. Examine whether there are cross-cultural differences in web response rates?
- II. Explain those cross-cultural differences with country-based indicators such as social and economic factors, technological factors and the country-specific survey climate

110 studies nested 64 manuscripts  
nested in 7 countries

# Inclusion & Exclusion Criteria

## Web-based survey

- Questionnaire on the web

## Other survey mode comparison

- email, mail, telephone,  
fax, face to face, other

## Response rates

- should be available or  
calculable
- survey country must be  
reported

## A split sample random experimental design

- respondents from the  
same population

## No mode switching

- remain in the mode they  
were randomly assigned

## The survey design

- should be the same for  
the compared modes (e.g.,  
same questions)

## Data Generation Model

Inference goal: generalizing beyond the studies included – **Random Effects Model (metafor – Viechtbauer, 2010)** (*no multilevel model possible due to too less variance on country-level*)

**Two Effect Sizes (Dependent Variable) and Metric** (*AAPOR 2000, Callegaro & DiSogra 2008*)

1. Web response rate (AAPOR RR5)

$$d = \frac{\text{number of web mode respondents}}{\text{number of invited and eligible subjects}}$$

2. Response Rate Difference Web and other Mode

$$d = \frac{\text{number of web mode respondents}}{\text{number of web mode invited and eligible subjects}} - \frac{\text{number of comp.mode respondents}}{\text{number of comp.mode invited and eligible subjects}}$$

## Seven countries included

Australia, Germany, The Netherlands, Slovenia, Sweden, United Kingdom, United States

## Independent Variables (Moderators)

Factor	Variable	Source	Description
Social and economic factors	Education	world bank	Education index
	GDP	OECD	Gross domestic product (GDP) at market prices is the expenditure on final goods and services minus imports by year and country.
	Annual population growth	world bank	annual population growth in a country by year and country
	Population ages 65 and over	OECD	The elderly population is defined as the share of people aged 65 and over. and the working age (15-64 years) population by year and country.
Technological factors	Internet coverage	world bank	Individuals using the Internet (% of population) by year and country
	Cellphone coverage	world bank	Mobile cellular subscriptions by year and country
	Internet users in %	world value survey	using the internet (daily, weekly, monthly, less than monthly, never) by year and country
Country-specific survey climate	Web response rate	calculated	study-level of current paper
	Other mode response rate	calculated	study-level of current paper
	Country-level aggregated Web response rate	calculated	country- level aggregated value of current paper
	Country-level aggregated other mode response rate	calculated	country- level aggregated value of current paper
	ISSP response rate	ISSP database	response rate by year and country to the last ISSP round

### Health surveys in the workplace: comparison of postal, email and World Wide Web methods

R. Jones and N. Pitt  
Department of Public Health, University of Glasgow, UK

Health surveys in the workplace are an important part of epidemiology, needs assessment and health promotion. Since the workplace is changing rapidly with the use of computer networks, we examined the feasibility, validity and cost of health surveys using email and the World Wide Web (WWW). Five hundred systematically sampled university staff in a convenience sample of 10 English universities were surveyed using either email alone, email plus a WWW form or postal questionnaire. Response rates, speed of response, validity and costs were examined. The postal survey obtained the best response rate: 75% as compared with 54% for email alone and 19% for the WWW, but it was also the most expensive at 10p per reply, with 75p for email, and 41p for the WWW. Most of the electronic responses were made within five days. In 1997, the increased response rate justified the higher cost of postal questionnaires. Email and WWW surveys are easy, quick and inexpensive to administer, and despite low response rates may be useful for pilot studies. The rapid changes in the spread and use of information technology means we have to keep reassessing the methods we use for health surveys in the workplace.

Key words: Information Technology; research methods; workplace.

Occup. Med. Vol. 48, pp. 558-558, 1998

Received 24 April 1997; accepted in final form 27 June 1998

This study was funded by SCORPIO (contract KCFR01/0007).

#### INTRODUCTION

The workplace has been identified<sup>1-3</sup> as an important site for health promotion. Evaluation of health promotion usually includes some form of survey. Until recently most surveys reported in the medical press have been conducted using postal questionnaires or face-to-face interviews, with an increasing number of telephone interviews and computer-assisted telephone interviews; few surveys have used email. A search of Medline<sup>4</sup> for the years 1987-97 identified 76 papers with the words 'postal survey' or 'postal questionnaire' in the title and nearly 1,500 with these words in the abstracts, 64 papers with 'telephone survey' or 'interview' in the title and 933 in the abstract and only two with 'email survey' in the title. However, the numbers of people connected at work to both computer networks within the organisation (Intranets) and to the Internet, is increasing, offering new survey methods. For example, general practitioners in Scotland have recently been offered a subsidised

scheme for connection to the NHSnet and most are now connected. Two methods for communication using the Internet were examined in this study: email (the sending of a message just using text) and the WWW in which a respondent can log on to a WWW site and complete an 'online form'. The majority of university staff are now connected to high speed local area networks and the Internet (for both email and the WWW). They therefore represent the workforce of the future. At the time of writing, the use of email for surveys had only been reported a few times in health<sup>5-7</sup> and other<sup>8-11</sup> surveys and more work was needed to compare these new survey methods with more traditional methods.

#### MATERIALS AND METHODS

To compare the use of email, email plus WWW and postal survey methods we surveyed employees of selected English universities. Three questions about exercise, tooth brushing and fruit consumption were asked. A convenience sample of 10 universities whose staff directories were available on the WWW was identified. A systematic sample completed.

### Experiments by country in %

More than 70% of the studies are US studies, followed by United Kingdom (11%) and the Netherlands (7%)

# Results:

## Descriptives & Sensitivity

### Web comparison mode in %

Web surveys are mostly compared to mail surveys (63%).

### Sensitivity Analysis

Based on the strong presence of US studies and mode comparisons with mail, we conducted three sensitivity analyses:

- Two random samples with a selection of US studies
- Mail comparisons only

All analyses succeed in replicating the subsequent findings

## Are there cross-cultural differences in web response rates?

	<b>Mean web response rate: 36%</b>	<b>Mean other mode response rate: 48%</b>	<b>Mean response rate difference: 12%</b>
<b>Heterogenous effect size?</b>	yes	yes	yes

Web Response Rate	.	<b>+ sig.</b>	<b>+ sig.</b>	<b>+ sig.</b>	n.s.
Response Rate Difference Web vs. Other Mode	<b>+ sig.</b>	<b>- sig.</b>	n.s.	<b>- sig.</b>	<b>+ sig.</b>

# Take Home Messages

## I. Are there cross-cultural differences in web response rates?

- Yes, the specific country has a significant influence on the success of a web survey. However, it can only explain less than 10% of the heterogeneity at country level.

## II. Do social and economic factors influence the success of web surveys?

- The higher the population growth and the lower the proportion of older people in a country the better do web surveys work.

## II. Do technological factors influence the success of web surveys?

- Internet and cellphone coverage show significant effects. The higher the Internet coverage, the higher is the web response rate and the smaller is the response rate difference. The higher the cellphone coverage, the better do web surveys work but the larger is the response rate difference.

## II. Does the country-specific survey climate influence the success of a web survey?

- Yes, the higher the country-specific response rates, the better do web surveys work.

# Limitations & Outlook

## Limitations

- ~73% of all studies conducted in the US -> need further evidence from other countries (more statistical power & better understanding moderating factors)
- All countries have a similar cultural background
- Searched English speaking literature only -> language bias problem
- Great degree of heterogeneity remains still unexplained

## Conclusion

- In summary, web surveys are particularly useful in countries with a younger, technology-oriented population that is generally open to surveys
- Our findings may help researchers who plan national and cross-national data collections to evaluate a web surveys response rate in comparison to other survey modes before the data collection
